My First Bitcoin

# Bitcoin Diploma

# Welcome to the Bitcoin Diploma

- My First Bitcoin: a nonprofit founded in El Salvador in 2021
- Free and open-source Bitcoin education for learners and educators
- First Diploma cohort: one public school in San Marcos, El Salvador, in 2022
- Focus: financial literacy, careful thinking and practical safety
- Not trading, speculation or promoting other tokens

# Our Mission and Values

**Independent, impartial and open-source Bitcoin education**

- **Accessibility:** in person, online or through print and PDF
- **Curiosity:** ask why, and admit what you do not know
- **Critical thinking:** check evidence, compare trade-offs
- **Community:** connect ideas to local life
- **Self-sovereignty:** more control means more responsibility

# Why This Diploma Exists

1. Explain the problem Bitcoin was designed to address
2. Explain Bitcoin's main response
3. Explain and practise the responsibility of holding and using bitcoin
4. Explore how Bitcoin may function as money in your community

# The Four-Module Path

- **Module 1, Problem:** How can money break?
- **Module 2, Solution:** Why was Bitcoin created, and how does it respond?
- **Module 3, Action:** How do I use and secure Bitcoin responsibly?
- **Module 4, Connect:** How does it all connect to this community?

# How Each Module Works

1. Learn a key idea
2. Show what you can explain or apply
3. Apply it to a comparison, question, scenario or demonstration
4. Explain the idea in your own words
5. Review how it connects to the next module

# Taking Part

- Describe ideas in your own words, and ask when a term is unclear
- Challenge ideas without attacking people
- State uncertainty when you are unsure
- Protect other people's private financial information
- Never pressure anyone to buy, sell or reveal how much they hold

# Learn First, Start Small, Verify

1. **Learn first.** Do not act because of excitement, fear or pressure.
2. **Start small.** Test new tools with an amount you can afford to lose.
3. **Don't Trust, Verify.** Check addresses, amounts, fees, sources and people.

# Module 1: Understanding Money

You will explain the money problems Bitcoin responds to.

# Opening Questions About Money

- Money is familiar, but it is not simple.
- Why do people need money, and what makes something money?
- Who can create or control your money, and why does it have value?
- Does your money buy the same amount today as in the past?
- Notice the difference between a fact and a preference.

# Why Money Exists

- Exchange lets people specialize: a farmer, a builder, a nurse.
- Direct exchange fails when the other person does not want what you offer.
- Money is accepted because people expect others to accept it later.
- It helps strangers cooperate across distance and time.
- Money is a tool for exchanging claims, not the valued thing itself.

# Functions and Properties of Money

- Medium of exchange: accepted in payment, reducing the need for barter.
- Unit of account: a shared unit for comparing prices and keeping records.
- Store of value: moves value from the present into the future.
- An item can perform one function better than another.

# Properties of Useful Money

- Durability: remains usable over time
- Portability: easy to move or transfer
- Divisibility: small and large amounts
- Fungibility: equal units are interchangeable
- Scarcity: supply is hard to increase
- Acceptability: others will receive it
- Verifiability: people can check it is genuine

# Barter and the Double Coincidence of Wants

- Barter is the direct exchange of one good or service for another.
- It works in small exchanges but struggles with many people and products.
- Double coincidence of wants: each must want what the other offers, at once.
- Goods may spoil or be indivisible, with no common unit for prices.
- Commonly accepted money separates selling from buying.

# Scarcity, Value, and Exchange

- Scarcity: choosing one use of a resource prevents another use.
- Value is not inside the object; it depends on people and circumstances.
- Exchange happens when both sides prefer what they receive.
- Opportunity cost, time preference, and trade-offs shape everyday choices.
- Scarcity alone does not guarantee value: demand matters too.

# Beginner Monetary History From Barter to Digital Money

- Money did not develop in one identical sequence everywhere.
- Early exchange relied on barter, gifts, obligations, and local records of debts.
- Commodity money: salt, beads, shells, livestock, copper, silver, gold.
- Standard coins helped accounting, but authorities could debase them.

# From Paper Claims to Digital Money

- Paper claims on metal were easier to move but required trusting the issuer.
- Gold standards legally linked a currency unit to a stated amount of gold.
- Bank and government money came to rest on records and promises.
- Most money today moves as digital records; a card or phone is an interface.
- Convenience grew, but so did dependence on issuers and intermediaries.

# Fiat Money

- Issued under government authority, not redeemable for a fixed amount of a commodity.
- "Fiat" is Latin for "let it be done", often understood as "by decree".
- Laws typically make it legal tender and require it for taxes.
- Network effects: people want it because others use it.
- Central banks, commercial banks, governments, and citizens each play a role.

# The Trade-Offs of Fiat Money

- Offers convenient payments, flexible credit, and tools for financial crises.
- That flexibility creates risk: a few institutions can change supply and cost.
- Institutions can restrict access or reduce purchasing power.
- Users trust banks, payment services, central banks, and governments.
- These rules are not fixed and can be open to neglect or abuse.

# Fractional Reserve Banking

- A deposit is the bank's liability: it owes you the balance.
- Banks keep only a fraction of deposits as immediately accessible reserves.
- A new loan usually creates new deposit money.
- Liquidity and solvency risks can trigger a bank run.
- A bank balance is the bank's promise to pay you.

# Inflation and Purchasing Power

- Price inflation: a sustained rise in the general price level.
- Purchasing power: the goods and services a unit of money can buy.
- A basket rising from 100 to 110 units: 100 units no longer buy it.
- Causes are many and debated; avoid single-factor explanations.
- Inflation affects savers, borrowers, lenders, and workers differently.

# Why the US Dollar Is a World Reserve Currency

- A reserve currency is held by central banks for international payments.
- Before the First World War, the British pound led this role.
- 1944 Bretton Woods: currencies linked to the dollar, the dollar to gold.
- In 1971, President Nixon ended official exchange of dollars for gold.
- The dollar remains the leading reserve currency, though its share can change.

# Why People Look for Alternatives

- People seek alternatives when they expect cash to lose purchasing power.
- Common choices: precious metals, real estate, and stocks.
- Each has trade-offs: storage, entry cost, volatility, or custody.
- No asset guarantees purchasing power in every period and situation.
- Bitcoin emerged as another proposed alternative, without a central issuer.

# Central Bank Digital Currencies (CBDCs)

- A CBDC is digital fiat money issued as a central bank liability.
- It differs from physical cash and from a commercial-bank deposit.
- Designs differ: some for institutions, others proposed for public use.
- It may speed settlement, but can also enable monitoring and limits.
- Digital does not mean decentralized, scarce, private, or verifiable.

# Questions to Ask About a CBDC

- Who issues the money?
- Who can hold or use it?
- What information is collected?
- Can a payment be blocked, limited, or reversed?
- Can the rules change?
- Can ordinary users verify the rules?
- What happens without electricity or internet?
- What legal protections exist?

# Review: How Can Money Break?

1. What makes the money you use useful in daily life?
2. Which of its rules depend on institutions you must trust?
3. How can money break?

# Module 2: How Bitcoin Works

You will explain why Bitcoin was created and what makes it different.

# Why Bitcoin Was Created

- Earlier digital payments relied on a trusted organization to keep the ledger
- Intermediaries can delay, charge, restrict, reverse, or fail; issuers can change supply
- Digital money was hard: data copies easily, and a central guard becomes a control point
- Bitcoin lets a peer-to-peer network agree on one history without a central ledger keeper
- "Bitcoin" means the network; "bitcoin" means the unit

# The Search for Digital and Decentralized Money

- The Cypherpunks explored how cryptography could protect privacy and freedom online
- Cryptography uses math to keep information private and prove an action is authentic
- Digital signatures prove who authorized something without revealing the secret key
- Private communication was not enough: people also needed to exchange value online
- The real goal: decentralized digital money, with no single issuer, server, or administrator

# Early Digital-Money Attempts and the Double-Spend Problem

- DigiCash: private digital payments, but it depended on one company and failed with it
- Hashcash: proof of work made unwanted email costly to send
- Bit Gold, b-money, reusable proof of work: ideas on digital scarcity, but incomplete
- BitTorrent: not money, but showed peer-to-peer sharing without a central server
- The open problem: double spending, because digital data copies perfectly

# How the Whitepaper Answered Double Spending

- 31 October 2008: Satoshi Nakamoto published *Bitcoin: A Peer-to-Peer Electronic Cash System*
- Peer-to-peer network: transactions are announced directly to participants
- Digital signatures: only the private key holder can authorize a spend
- Blocks and mining: miners compete with proof of work to add the next block
- Nodes verify the rules; the valid chain with the most accumulated work is the shared record

# Digital Scarcity and Credible Scarcity

- Digital information is normally easy to copy
- Digital scarcity: the system rejects invalid copies and spending the same unit twice
- Bitcoin combines signatures, a public history, proof of work, and rule verification
- Scarcity is credible when rules are public and independently verifiable
- No single issuer can quietly change the supply for everyone

# The Blockchain - Bitcoin’s Public Ledger

- Banks each keep their own ledger; Bitcoin uses one shared, public, decentralized ledger
- A block is like a page of transactions in precise chronological order
- Blocks are chained together in order, forming the "blockchain"
- A new block is added approximately every 10 minutes
- The ledger is append only, so it is considered "immutable"

# Decentralization

- Centralized systems have a controlling point: a bank, payment company, or government
- Bitcoin has no central office to create accounts, change balances, or approve membership
- Open-source software, independent nodes, competing miners, and many copies of the ledger
- Rule changes require voluntary adoption by participants
- Trade-offs: slower coordination, more user responsibility, no central support desk

# Digital Signatures

- A wallet uses a private key to sign and authorize a transaction
- Only the holder of the required private key can authorize the spend
- The network verifies the signature without learning the private key
- No bank or central operator has to give permission
- Whoever obtains the key can usually spend; a lost key may mean lost bitcoin

# Peer-to-Peer Transfer

- Participants interact through a network without a central coordinator
- A user signs a transaction and broadcasts it; no Bitcoin operator approves it
- The recipient does not need an account at the sender's bank
- Users can still choose intermediaries, but then depend on their rules and security
- A valid payment to the wrong address usually cannot be reversed

# Users, Nodes, and Miners

- Users receive, hold, and send bitcoin, with their own keys or a custodian
- Nodes independently verify the rules and reject invalid data
- Miners build candidate blocks and compete through proof of work
- Developers propose software changes; participants choose whether to run them
- The roles limit one another: no single role controls the network

# Proof of Work

- Miners repeatedly hash a candidate block, searching for a result below a target
- There is no shortcut: finding a result is costly, checking it is quick
- Each valid block added after a transaction adds another confirmation
- Difficulty adjusts so blocks arrive about every ten minutes on average
- The chain with the most accumulated work is the shared history

# Finite Supply

- Maximum supply: 21 million bitcoin, issued through the block subsidy to miners
- Every 210,000 blocks the subsidy halves (a "halving"), roughly every four years
- The subsidy began at 50 bitcoin per block; since the 2024 halving it is 3.125
- Nodes enforce the limit by rejecting blocks that create too much bitcoin
- A network rule, not a physical law: it holds while participants enforce it

# Satoshis and Unit Bias

- One bitcoin divides into 100,000,000 satoshis (sats)
- A sat is the smallest unit recorded on Bitcoin's base layer
- You do not need to buy or use a whole bitcoin
- Unit bias: wrongly feeling that a low price per unit means cheaper or more accessible
- 100,000 sats and 0.001 bitcoin are the same amount

# Bitcoin as Sound Digital Money

- Durability: the ledger is copied across many nodes
- Portability: value moves over a communications network
- Divisibility: 100,000,000 sats per bitcoin
- Fungibility: equal amounts spend under the same rules
- Scarcity: public issuance rules, 21 million maximum
- Verifiability: a node can check supply and ownership
- Acceptability: growing in some places, still limited

# Functions of Money: Benefits and Trade-Offs

- Store of value: predictable supply, but a volatile market price
- Medium of exchange: moves without a bank; acceptance, fees, and tools vary
- Unit of account: amounts in bitcoin or sats, but most goods are priced in fiat
- Benefits: direct ownership, predictable supply, global transfer, open participation
- Trade-offs: volatility, security responsibility, irreversible errors, changing fees, limited acceptance

# Bitcoin, Stablecoins, and Other Crypto-Assets

- Digital assets can look alike on screen but rely on very different systems
- Bitcoin: public supply rules, with no issuer creating bitcoin outside them
- Stablecoins: designed to track another value; rely on issuers, reserves, and counterparties
- Other digital assets: issuance, control, and what you can verify vary by asset
- The comparison only clarifies Bitcoin; it is not a recommendation

# Questions to Ask About Any Digital Asset

- Who controls issuance or changes to the rules?
- What can I verify independently?
- Who holds the keys?
- Which company, issuer, or other counterparty must I trust?
- Am I judging the asset itself, or the service holding it for me?

# Learning and Responsible Use Are Not Trading or Promotion

- Learning how Bitcoin works differs from chasing short-term price changes
- Trading and speculation can bring rapid decisions, loss, and platform risk
- Token promotion can create conflicts of interest
- This Diploma helps you explain Bitcoin, ask better questions, and decide more safely
- It gives no investment advice on what to buy, sell, or hold

# Bitcoin Origin Timeline

- 31 October 2008: Satoshi Nakamoto publishes the Bitcoin whitepaper
- 3 January 2009: the Genesis Block starts the Bitcoin network
- 12 January 2009: first recorded person-to-person transaction, to Hal Finney
- 22 May 2010: 10,000 bitcoin paid for two pizzas (Bitcoin Pizza Day)
- Satoshi's identity remains unknown; no central company owns Bitcoin

# Participant Empowerment, Risk, and Responsibility

- Public rules, a peer-to-peer network, and signatures give participants meaningful roles
- No single role controls the network for everyone
- No central authority can recover access or reverse many errors
- Self-custody: no company can freeze your bitcoin, or restore a lost seed phrase
- Responsibility is not acting alone: use education, peer review, and small tests

# Review: How Does Bitcoin Respond to Fiat Problems?

1. How do public rules, finite issuance, peer-to-peer transfer, and verification answer fiat concerns?
2. How do the roles of nodes and miners differ?
3. Why must double spending be prevented?
4. What new responsibilities arise when a person controls their own keys?
5. Does Bitcoin have value to you? Does its current price represent its value?

# Module 3: Using Bitcoin Safely

Explain who controls the keys, receive or send safely, respond to scams, and show recovery readiness.

# Three Rules for Safe First Steps

- Share receiving information, never secrets
- Pause before approving a send
- Keep mistakes small: stop and ask when a request is unclear or rushed
- Practice uses a simulation, test funds, or an educator-approved amount
- You never need to buy bitcoin to complete the Diploma

# Wallets

- A wallet manages the information needed to receive and authorize transactions
- Bitcoin is recorded on the shared ledger, not stored inside a phone
- The first question about any wallet: who controls the keys?
- Check who can authorize a payment and how access is recovered
- Start with your educator's prepared environment, not a stranger's recommendation

# Addresses

- An address is public receiving information for an on-chain payment
- It is not a password and cannot authorize spending by itself
- Take it from the intended wallet's receive screen: scan or copy, never retype
- After copying, compare the destination with the trusted receiving screen
- An on-chain address and a Lightning invoice are different

# Keys

- A private key is secret: it allows a wallet to authorize spending
- A public key helps verify a signature without revealing the private key
- A signature proves authorization; the private key is not inside the transaction
- Beginners should not copy or handle individual private-key strings
- No legitimate educator, company, or developer needs your private key or seed phrase

# Seed Phrases

- An ordered list of words (commonly 12 or 24) that backs up a wallet's keys
- Order and spelling matter
- Whoever has it can often restore the wallet and spend: it is full access
- Keep it offline; never photograph, email, message, or type it into a website
- If it may have been seen or copied, treat it as compromised

# Custodial and Non-Custodial Use

- Custody asks: who controls the keys required to spend the bitcoin?
- Custodial: a company or another person controls the keys
- A custodial balance is a promise from the custodian
- Self-custodial: you control the keys and handle recovery through a backup
- If a company must approve your withdrawal, it is probably custodial

# Hot and Cold Wallets

- A hot wallet keeps keys on an internet-connected device, such as a phone
- Hot wallets are convenient for regular payments but have a larger attack surface
- A cold wallet keeps signing keys away from internet-connected general-purpose devices
- A hardware wallet is a dedicated device that keeps keys isolated
- The device, backup, and recovery process still need protection

# Wallet Recovery and Seed Phrase Testing

- A recovery plan restores the expected wallet without exposing recovery information
- Practice only with educator-prepared, empty, or simulated materials
- Follow the wallet's official recovery method, privately, away from cameras
- Confirm the expected training wallet, then reset the temporary material
- Never enter a real recovery phrase into a website, message, or form

# Receiving Bitcoin

- Receiving cannot send funds out, but it still needs careful checking
- Use the intended wallet and identify on-chain or Lightning
- Share only the address, QR code, or payment request
- A message or screenshot saying "sent" is not proof: check your own wallet
- Confirmations add confidence but do not repair a wrong address or scam

# Sending Bitcoin

- A valid Bitcoin transaction is usually irreversible
- Confirm the recipient, purpose, and payment method through a trusted channel
- Compare the destination with the trusted receiving screen
- Check the amount, unit, fee or expiry, and final summary
- Use a small test when the process is unfamiliar

# Verification, Block Explorers, and Irreversible Transactions

- A transaction ID (TXID) identifies an on-chain transaction
- A block explorer shows public data: status, destination, amount, fee, confirmations
- It cannot prove why a payment happened or whether someone is trustworthy
- Later confirmations add confidence but do not fix a wrong destination
- Searching an address or TXID may reveal your interest to the explorer's operator

# Safety Checklist

- Someone impersonates support or an educator
- Pressure to act urgently
- Requests for secrecy
- Promises of guaranteed returns
- Asking you to send bitcoin first
- A changed destination
- Requests for keys or recovery words
- Requests for remote access or an advance fee

# The Safe Response to a Red Flag

- Pause. Share nothing. Send nothing. Close the channel.
- Verify independently through a known source
- Ask for help without revealing secrets
- Use official instructions; beware sponsored results, message links, and look-alike sites
- Start with a simulation or small approved amount; never borrow to experiment

# Acquiring and Exchanging Bitcoin

- Pathway awareness, not financial advice
- Pathways include earning, peer-to-peer exchange, exchanges, brokers, ATMs, and kiosks
- Each has different cost, custody, privacy, fraud, and legal trade-offs
- This Diploma does not recommend a provider or path
- KYC identity checks can help recovery but link identity to financial activity

# On-Chain and Lightning Payments

- On-chain payments are recorded in Bitcoin's blockchain and gain confirmations
- Lightning is a payment network built on Bitcoin for fast, frequent payments
- A Lightning payment usually completes or fails quickly
- A Lightning wallet can still be custodial or self-custodial
- Confirm which path the recipient expects before paying

# Practical Competency Check Observed by an Educator

- Your educator observes you in a prepared, simulated, or low-stakes environment
- Navigate the prepared wallet and check receiving information
- Complete or safely simulate a receive or send
- Show recovery readiness while keeping all secrets private
- Not ready yet? You receive feedback, more practice, and another opportunity

# Review: What Does Self-Custody Responsibility Mean?

1. A friend sends a payment request while an unfamiliar support account says act now: what do you check?
2. What can you share to receive bitcoin, and what must remain secret?
3. How do you protect a recovery plan?
4. What five things do you verify before approving a send?
5. Who controls the keys in custodial and self-custodial use?

# Module 4: Bitcoin in Your Community

You will see how Bitcoin can function as money in your local context.

# The Connect Stage

- Connect Modules 1 to 3 to a real local need or opportunity
- Bitcoin is one global protocol used under different local conditions
- Internet, phones, laws, taxes, banks, fees and language shape what is useful
- You are not expected to adopt Bitcoin or call it the best option
- Use the Module 3 safety checklist throughout this module

# Your Local Module 4

- Apply an idea from Modules 1 to 3 to a real local need
- Connect, compare, practise safely, then explain what you learned
- Explore earning, saving, receiving, spending, merchant or community use
- Get to know local tools and organisations without having to use them
- A local example is not proof that it works everywhere

# Practical Workshops and Demonstrations

- Three stages: Presentation, Practice, then Production
- Practise with safe materials or a very small amount
- Tasks include custody checks, receive screens and comparing fees
- Spot scam signals and map local resources or payment flows
- The result is an explanation or skill, not just a transaction

# Before Any Live Demonstration

- Check the tool and instructions recently
- Explain recovery and what happens if something fails
- Say whether real funds are involved; no pressure to install or disclose
- Keep amounts small enough that a total loss is a lesson
- Have an offline or no-funds alternative and a plan to stop

# Local Bitcoin Tools and Resources

- Wallets, exchanges, peer-to-peer markets, merchant tools, maps and meetups
- Availability and quality can change quickly
- Verify purpose, custody, source, code, recovery and privacy
- Also check cost, compatibility, safe local support and local law
- Tools named in class are examples, not endorsements

# Lightning Payments Where Locally Appropriate

- Lightning can make fast, small Bitcoin payments practical
- Useful when an on-chain fee is too large for the payment
- Check custody, funding, backup, fees, limits and failure handling
- Confirm how the recipient knows the payment arrived

# Invoices, Addresses and a Guided Payment

- A Lightning invoice is a request for one specific payment
- A Lightning address looks like an email but depends on a provider
- Check recipient, amount, unit and fee before approving
- Both sides confirm the result in their own wallets
- Payment convenience and custody security are separate questions

# Daily-Life Bitcoin Use

- Bitcoin can function as money in several ways; spending is only one
- Earning, saving, receiving, sending, spending, pricing and donating
- Ask: what existing problem does Bitcoin address here?
- Ask: is it better than the available alternative?
- Ask: what new responsibility or risk does it create?

# Local Spending and Receiving Scenarios

- Five scenarios: a small purchase, payment for work, a family transfer
- Also a refund after an on-chain payment and a community donation
- Use locally familiar goods and services
- The payment reasoning matters more than the item
- Explain the complete flow before approving any payment

# Local On-Ramp and Off-Ramp Pathways

- On-ramp: from local money, work or assets into bitcoin
- Off-ramp: from bitcoin into local money, goods or services
- Compare the complete route, not only the first fee
- Check you can withdraw to a wallet you control
- Meet in public places and never reveal your holdings

# KYC and No-KYC Trade-Offs

- KYC may meet local rules, connect to banks and support recovery
- KYC also creates lasting data risk from breaches or policy changes
- No-KYC may improve privacy but bring less support and more fraud risk
- Privacy is the ability to control information about yourself
- Never break local law or risk physical danger for privacy

# Circular Economies

- People earn, spend, save and exchange bitcoin within a community
- Can reduce dependence on distant services and build local relationships
- Can fail with little demand, poor tools, weak security or pressure
- Healthy loops are voluntary and solve real problems for several participants
- Adoption numbers alone do not show usefulness

# Merchant Use Cases

- A merchant needs more than a receive button
- Decide pricing units, on-chain or Lightning, and custody model
- Plan device access, conversion, confirmation and refunds
- Know the required records and what staff do when systems fail

# Community Use Cases and Shared Custody

- Pay local workers or creators and receive donations transparently
- Support savings groups, remote workers and local producers
- Provide emergency support where ordinary payments are unavailable
- An organizer holding funds for others becomes a custodian
- Shared funds need clear rules, records and access controls

# Local Resource Maps and Community Discovery

- Maps and directories help find merchants, educators and meetups
- Listings can be incomplete or outdated
- Contact before a special journey and bring another way to pay
- Never reveal seed phrases, balances or home addresses at meetups
- Good communities respect your choices without one-leader dependence

# Review: How Do the Problem, Solution, and Safe Action Connect to Your Community?

1. What real need did your local example address?
2. Which function of money was involved?
3. Was value moved on-chain, through Lightning, or both?
4. Who controlled the keys, and what were the strongest benefit and most serious risk?
5. How did local law, infrastructure, language, or culture affect the result?

# Next Steps

You now have a foundation. Protect it by moving slowly.

# Review Your Learner Journey

- Return to the answers you wrote before the course; do not erase them
- What is money? Who can create or control the money you use?
- Has its purchasing power changed?
- Record your answer now, and what changed or became clearer

# Choose One Safe Next Step

- Review a question and check it against a reliable source
- Practise one skill safely, such as checking an address
- Make a personal safety plan before taking on more risk
- Explain Bitcoin to another person in plain language
- Contribute: proofread, give feedback or explore educator training

# A Safety Reminder

- Never share a seed phrase or private key
- Verify recipient, network, address, amount and fee
- Transactions are usually irreversible
- Use a small test for a new process
- Do not act under pressure or promises of profit
- Verify wallet software and support contacts
- Know who holds the keys
- Test recovery before funds depend on it
- Keep balances and security private
- Check current local laws, taxes, fees and services

# Keep Learning with My First Bitcoin

- The My First Bitcoin Education Network connects independent educators and communities
